

Engineered Materials (SC221)

Packing Fraction of single component crystal structures

- Hexagonal close-packed (hcp): 0.74
- Face-centered cubic (fcc): 0.74
- Body-centered cubic (bcc): 0.68
- Simple cubic: 0.52
- Diamond cubic: 0.34

Simple cubic (52%)

Body-centered cubic (68%)

The number of atoms in the unit cell is not the same as the coordination number (number of nearest neighbours). In the **Body Centered Cubic (bcc)** structure above the number of atoms in the unit cell is 2 but the number of nearest neighbours is 8. The (bcc) structure is not as tightly packed as the (hcp) or (fcc) structures, with the atoms occupying only 68.02% of the available space.

The basis crystal structure of group IV crystals is a FCC.

Si & Ge are Diamond Structure (Zincblende) crystals

Find out APF (atomic packing fraction) of Diamond structure.

Note in a FCC there are 4 atoms per unit cell, whereas in a diamond structure or a zincblende structure there are 8.

So APF will change.

Diamond is said to be the hardest material, yet its APF is even lower than that of a SC structure.

APF = vol. of atoms in unit cell/vol. of unit cell

$$= (z \times \text{vol. of one atom}) / \text{vol. of unit cell}$$

Density = mass of all atoms in the unit cell/vol. of the unit cell

$$= (z \times M) / (N_A \times a^3)$$

where M = molar mass of the atom/element

N_A = Avogadro number (no. of atoms per mole)

So, density is a function of i) a (lattice constant) and ii) ratio of M/N_A .

Material	'a' Lattice constant (Å)	Crystal structure	Atomic No.	M (in amu/mole)
C (diamond)	3.567	Diamond (FCC)	6	12
Si	5.431	Diamond (FCC)	14	28
Ge	5.658	Diamond (FCC)	32	72
GaAs	5.653	Zinc blende (FCC)		144
CdS	5.832	Zinc blende (FCC)		144
ZnS	5.42	Zinc blende (FCC)		97

Considering the valence band and conduction band formation in Si and/or Ge crystals, how do you think they would conduct?

Or they are perfect insulators?

At absolute zero temperature semiconductors are perfect insulators.

At room temp.

$$n_i = 1.5 * 10^{10} \text{ cm}^{-3} \text{ (Si)}$$

$$n_i = 12.5 * 10^{13} \text{ cm}^{-3} \text{ (Ge)}$$

$$n_i = 1.8 * 10^6 \text{ cm}^{-3} \text{ (GaAs)}$$

It rises with rise in temp.

Why?

Energy vs. crystal momentum for a semiconductor with an indirect band gap, showing that an electron cannot shift from the highest-energy state in the valence band (red) to the lowest-energy state in the conduction band (green) without a change in momentum. Here, almost all of the energy comes from a photon (vertical arrow), while almost all of the momentum comes from a phonon (horizontal arrow).

(a) Direct

(b) Indirect

Direct and indirect electron transitions in semiconductors:
 (a) **direct transition with accompanying photon emission;**
 (b) **indirect transition via a defect level.**

Comparison between Direct and Indirect bandgap materials

This may be a situation which gives you an opportunity to engineer the material. In this example we may see how a $\text{Al}_x\text{Ga}_{1-x}\text{As}$ may be converted between GaAs ($x=0$) to AlAs ($x=1$) material.

In the ternary alloy $\text{Al}_x\text{Ga}_{1-x}\text{As}$ all of these conduction band minima move up relative to the valence band as the composition x varies from 0 (GaAs) to 1 (AlAs). However, the indirect minimum X moves up less than the others, and for compositions above about 38 percent Al this indirect minimum becomes the lowest-lying conduction band. Therefore, the ternary alloy AlGaAs is a direct semiconductor for Al compositions on the column III sublattice up to about 38 percent, and is an indirect semiconductor for higher Al mole fractions. The band gap energy E_g is shown in color on Fig. 3-6(c).

The variation of energy bands for the ternary alloy $\text{GaAs}_{1-x}\text{P}_x$ is generally similar to that of AlGaAs shown in Fig. 3-6. GaAsP is a direct semiconductor from GaAs to about $\text{GaAs}_{.55}\text{P}_{.45}$ and is indirect from this composition to GaP (see Fig. 6-19). This material is often used in visible LEDs.
